

Parking Support Brake function (rear-crossing vehicles)*

If a radar sensor detects a vehicle approaching from the right or left at the rear of the vehicle and the system determines that the possibility of a collision is high, this function will perform brake control to reduce the likelihood of an impact with the approaching vehicle.

Examples of system operation

The system will operate in situations such as the following if an object is detected in the traveling direction of the vehicle.

- **When reversing, a vehicle is approaching and the brake pedal is not depressed, or is depressed late**
